SUBJECT: Task 3.1 – “Before” Multimodal Data Collection – Bend Galveston Corridor Plan P13198-000

The City of Bend is designing improvements along NW Galveston Avenue from NW 14th Street to the Deschutes River. One of the goals for these improvements is to make the corridor a safer and more attractive environment for multimodal travel. To support this effort, DKS Associates collected traffic data to quantify current multimodal travel along the study corridor. Volumes for bicycles, pedestrians, and motor vehicles was supplemented with observational data quantifying motorist yielding rates to pedestrians crossing the street and the comfort level of bicyclists. A review of recent crash records was also performed to characterize the safety history at the study intersections. The intent is to collect the same data after the preferred design improvements are complete to assess how the project altered traveler behavior.

Study Area

Galveston Avenue serves an important role in Bend's transportation system. As one of only four river crossings to downtown, it connects the west side neighborhoods to Bend's core.

Galveston Avenue is classified as a minor arterial roadway in the Bend Urban Area Transportation System Plan (TSP)¹ with a posted speed of 25

miles-per-hour (mph). The bike lanes on Galveston Avenue provide a backbone connection in Bend's Bicycle and Pedestrian System Plan,² and the route is part of the Oregon Scenic Bikeway network.³ Galveston Avenue forms the main east-west bike route through central Bend, connecting with a recently completed project on Riverside Boulevard and Franklin Avenue.⁴ The bike network extends north-south through bike lanes on 14th Street and shared roadways at 12th Street and Harmon Boulevard. There are no other projects identified in the TSP in the study area.

⁴ Project ST11FA. Adopted 2013-2018 Capital Improvement Program.

<http://www.bend.or.us/modules/showdocument.aspx?documentid=14209>

Six intersections were chosen for study as shown in Figure 1. All of the intersections are two-way stop controlled with traffic flowing mostly unrestricted on Galveston Avenue. The exception is the Galveston Avenue/Harmon Boulevard intersection, where westbound vehicles on Galveston Avenue are prohibited from making a left turn, and movements off of Harmon Boulevard are restricted to right turns only. The roadway has one 12-foot travel lane in each direction, with a 10-foot shared two-way left turn lane (TWLTL) beginning just west of Harmon Boulevard and continuing until the splitter islands at the 14th Street roundabout. Parking is prohibited along both sides of the roadway and standard 5-foot bike lanes are present in both directions. Sidewalks are present along most of the roadway with gaps on the south side west of Federal Street to the midblock alley and east of Harmon Boulevard to the bridge.

Bicycle and Pedestrian Volumes

Bicycle and pedestrian volumes were collected at all six study intersections on November 12th and 13th of 2013 and are attached. These counts were taken over a two-hour period from 4-6 p.m. The recorded volumes are shown in Figure 2. Bicycle and Pedestrian volumes vary seasonally, and results from Bend’s Bicycle and Pedestrian Documentation Project⁵ suggest volumes could be four to five times higher during the summer seasonal peak.

Two of the intersections, 12th Street and Columbia Street, feature a continental-style painted crosswalk across Galveston Avenue along the west leg of the intersection. There are three transit stops for Cascade East Transit (CET) Route 11 in the study area as shown in Figure 2, scheduled for two arrivals during the peak hour.

The highest pedestrian volumes crossing Galveston Avenue occur at the painted crosswalks, indicating high compliance in using the marked crossings. Bike volumes were highest at Galveston Avenue/Harmon Boulevard, where 46 bikes were recorded entering the intersection. The lowest volumes were at Columbia Street/Elgin Avenue/Harmon Boulevard (11 bikes) and Galveston Avenue/13th Street (27 bikes). Figure 3 shows bicycle movements at each intersection along Galveston Avenue categorized as through, crossing, entering, or exiting the corridor. The roadways of 12th Street and Harmon Boulevard are the most popular places for bicyclists to enter, exit, and cross Galveston Avenue, consistent with their designation as shared roadways.

Motor Vehicle Volumes

Motor vehicle volumes were collected at all six study intersections on November 12th and 13th of 2013 during the same two-hour period as the bicycle and pedestrian counts and are attached. The volumes for the peak hour are shown in Figure 4. The majority of the traffic volumes on Galveston Avenue travel through the corridor, indicated by the low turn movement volumes. The highest turning volumes are at the intersection of Galveston Avenue/Harmon Boulevard where just over 19% of eastbound traffic turns north. Columbia Street has the most motor vehicles crossing Galveston Avenue.

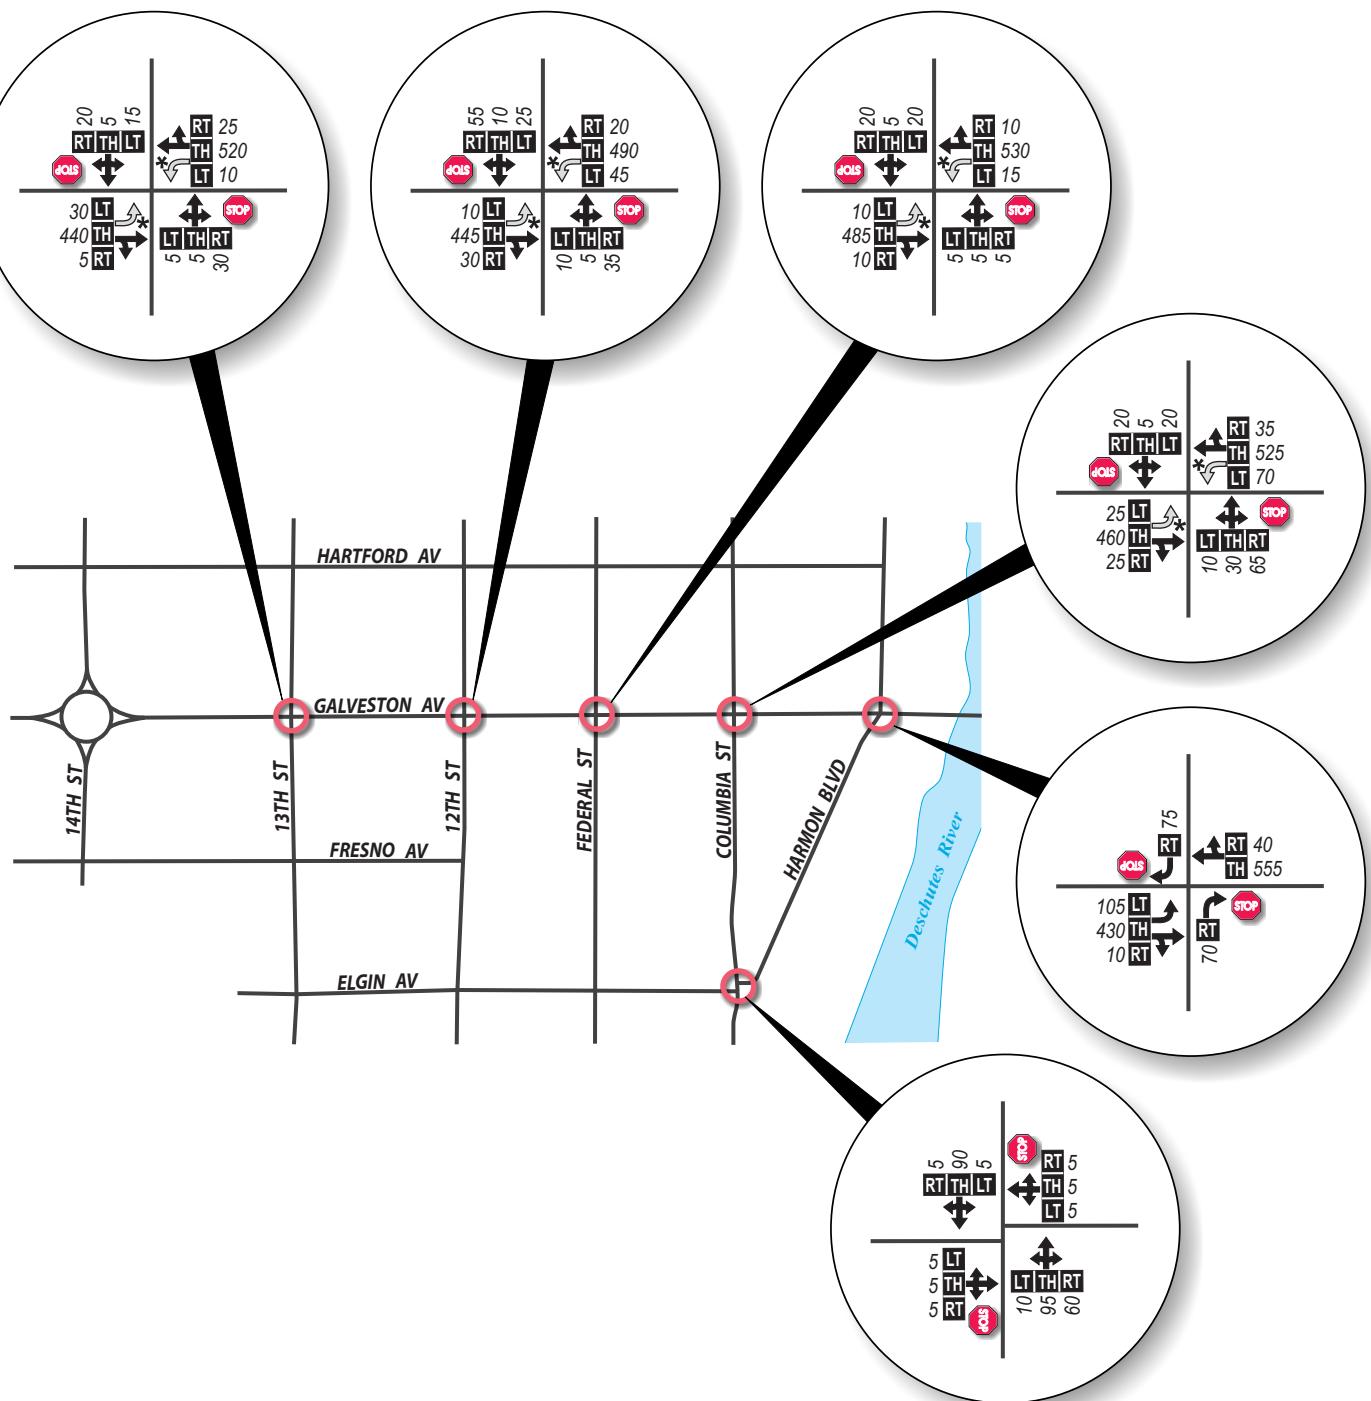

Using the modeling software Synchro™ 8, traffic operations at the study intersections were evaluated using 2010 Highway Capacity Manual methodology for two-way stop controlled intersections. The results are summarized in Table 1 and computations are attached. The City of Bend sets mobility standards for two-way stop controlled intersections by average delay for the critical lane group, which must be less than or equal to 50 seconds during the peak hour.⁶ Currently, the southbound left turn at the intersection of Galveston Avenue/Columbia Street does not meet the City’s mobility standard in terms of delay during the p.m. peak hour.

Table 1: Existing Intersection Operations (PM Peak Hour)

Intersection	Critical Lane Group Average Delay (sec./vehicle)	Level of Service (LOS) (Major / Minor)	Critical Lane Group Volume to Capacity (V/C)
Galveston Ave./13 th St.	22.4	A/C	0.17
Galveston Ave./12 th St.	24.5	A/C	0.34
Galveston Ave./Federal St.	23.1	A/C	0.19
Galveston Ave./Columbia	53.6	A/F	0.52
Galveston Ave./Harmon	14.7	A/B	0.18
Elgin Ave./Columbia St./ Harmon Blvd.	10.3	A/B	0.02

Values above Bend’s mobility standards are bold and highlighted.

Vehicle Yielding Rates to Pedestrians

To quantify how the preferred design improvements may alter driver behavior, vehicle yielding rates to pedestrians were collected at two of the study intersections to establish a baseline condition. The intersections at Columbia Street and Federal Street were selected so that both a marked and non-marked crosswalk location would be included. The study protocol was based on methodology described in “TCRP Report 112/NCHRP Report 562: Improving Pedestrian Safety at Signalized Crossings.”⁷

General population pedestrians were observed crossing Galveston Avenue at these two locations on-site and in video recorded as part of the vehicle counts at each intersection. This was supplemented with staged crossings at each location conducted by DKS staff. During the afternoon peak period, 12 – 2 p.m., each intersection was observed for an hour in alternating half-hour periods. When no general population pedestrians were using the intersection, crossings were staged to ensure at least 40 crossing events were captured in the hour. Further observations were recorded for both intersections from two-hour videos recorded from 4 – 6 p.m. as part of the traffic volume counts.

For every crossing the following information was recorded:

- Number of pedestrians and whether it was a staged crossing.
- Time, in seconds, elapsed between visible intent to cross and the first yielding vehicle. If no delay was observed or no vehicles were present a value of zero was recorded.
- Number of yielding vehicles in the near direction of travel (those approaching from the left).
- Number of non-yielding vehicles in the near direction of travel.
- Number of yielding vehicles in the far direction of travel (those approaching from the right).
- Number of non-yielding vehicles in the far direction of travel.

Consistent with Oregon law, the staged pedestrian approached the crossing, made an attempt to cross, and waited until motorists in the closest lane of travel stopped or yielded the right-of-way. An attempt to cross, initiated by placing one foot into the roadway, was only made when approaching vehicles were beyond acceptable stopping sight distance (i.e., far enough from the crossing location) based on the posted speed of the roadway.⁸ They then began crossing, but waited to enter the further lanes until motorists had again stopped or yielded. Oregon law requires vehicles, including bicycles, to yield to pedestrians in their lane or in either lane adjacent to theirs. Vehicles that did not stop when required to were counted as not yielding. Vehicles that slowed down without passing through the crosswalk to permit the staged pedestrian to safely cross were considered yielding vehicles. Vehicles that were too close to comfortably stop – estimated as being inside the stopping sight distance – were not counted.

A Pedestrian's View of the Crosswalk on Galveston Ave. at Columbia St.

⁷ Transportation Research Board. “TCRP Report 112/NCHRP Report 562: Improving Pedestrian Safety at Unsignalized Crossings.” 2006. <http://onlinepubs.trb.org/onlinepubs/nchrp/nchrp_rpt_562.pdf>. This report is based on Transit Cooperative Research Program Project D-8 and National Cooperative Highway Research Program Project 3-71.

⁸ AASHTO. “A Policy on Geometric Design of Highways and Streets.” Sixth Edition, 2011.

A summary of the results is shown in Table 2. During the afternoon period, both intersections had yielding rates of over 80%, with yielding rates at Columbia Street (marked crossing) being slightly higher. During evening observations, yielding rates were lower and over 90% of pedestrians crossed at Columbia Street.

Bicyclist Lateral Positioning

Bicyclist lateral positioning within the bike lane was used to characterize bicyclist comfort along Galveston Avenue. Using in-person observations and recorded video records, each passing bicyclist was classified by their choice of riding location. Three positions were defined within the bike lane – centered, near the curb edge, or near the inside edge (motor vehicle travel lane). Bicyclists riding in the motor vehicle travel lanes or on the sidewalks were also recorded. The position of a bicyclist within the bike lane can indicate their level of comfort and confidence – given a range of available riding positions, more comfortable or confident cyclists will likely ride closer to the traffic side of a bike lane. Bicyclists positioning themselves near the curb or on the sidewalk are thought to be less comfortable or confident. It should be noted that other factors can influence a bicyclist's position such as debris, drains, and adjacent parked cars. These observations were taken prior to the winter season, during which more road debris and gravel collect toward the curb. Drain grates, though bike-friendly in design, are present curbside along the corridor and riders may actively avoid them. On street parking introduces the danger of being hit by opening doors, but this is not an issue for the existing Galveston Avenue conditions.

During the in-person staged pedestrian crossings described above, bicyclist information was also recorded by DKS staff. This was supplemented with video records taken midblock on Galveston Avenue between 12th Street and Federal Street from 4 – 6 p.m. Results are shown in Figure 5. Over 85% of the 61 observed bicyclists positioned themselves in the center of the bike lane or near the inside edge, divided evenly between the two positions. Driver behavior was also observed in the recorded video, where 10 drivers were seen to pass bicyclists. Of these, all drivers moved away from the bicyclists when passing them and 40% moved over a foot into the TWLTL.

Curbside Drain Grate in the Bike Lane

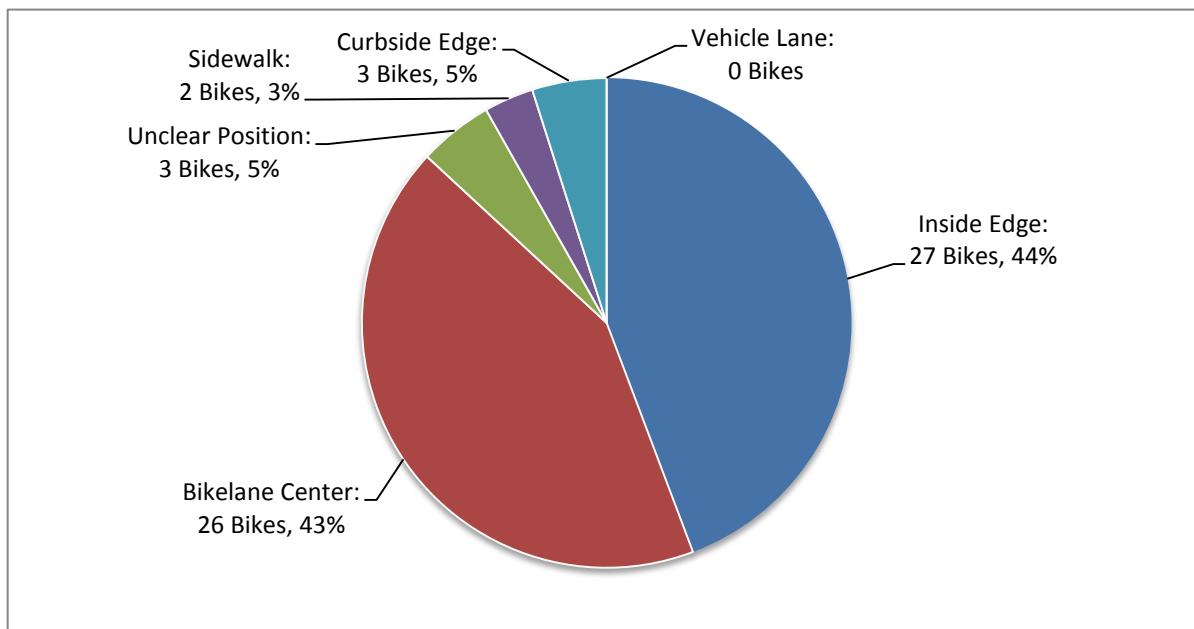

Figure 5: Bicyclist Positioning Results

Crash Records

The City of Bend has undertaken significant recent work to determine the causes, types, and characteristics of crashes in the city, and how reductions to crashes can be achieved given limited resources. Bend undertook a Multimodal Traffic Safety Program⁹ in 2012 to screen and evaluate the transportation system and look at countermeasures at locations with the potential to reduce crashes. Bend established five focus areas for reduction: fatal and injury crashes, alcohol-involved crashes, speed-involved crashes, pedestrian and bicyclist crashes, and roadway departure crashes. The program did not identify any high-crash locations within this project’s study area, but does provide a context and framework for evaluating road safety in Bend.

Crash records at the study intersections were obtained from the Oregon Department of Transportation (ODOT)¹⁰ for the previous five years (2008 – 2012) and are attached. A total of 15 crashes were recorded during this time period. The collisions are summarized in Table 4 by severity and vehicle movement. The majority of crashes (80%) involved minor or no injuries, and there were no fatal crashes. No crashes involved drugs, alcohol, or speeding. Most crashes involved turns (47%) and rear-end collisions (33%). There were no roadway departure crashes.

There was one crash involving a pedestrian, an injury B crash, at the intersection of Galveston Avenue/Federal Street. An injury B crash involving a bike was recorded at the intersection of Galveston Avenue/13th Street. Both of these crashes occurred during clear days and involved a left turning vehicle failing to yield. In the pedestrian collision the vehicle was turning left onto Galveston Avenue, while the bike was struck by a vehicle turning left off Galveston Avenue. The most severe crash within the study area was an injury A at the intersection of Galveston Avenue/13th Street. Occurring during a clear day, it was an improper left turn off Galveston Avenue resulting in an overturned vehicle.

Crash rates, commonly referred to as crashes per million entering vehicles (MEV), compare the total number of collisions over the last five years to the total volume of traffic that entered the intersection. The crash rates are included in Table 3. It is generally accepted that intersections are flagged for review for crash rates greater than 1.0. Crash rates can also be compared to ODOT’s statewide average rates.¹¹ From 2008 to 2012, minor arterials in urban cities averaged 3.10 crashes per MEV. Based on this, there does not appear to be major safety concerns at any of the study intersections.
